- **__init__.py**: Marks the directory as a Python package and explicitly defines the public interface by importing specific functions from the internal modules.
- **data.py**: Loads the delivery data from a CSV file and splits it into training and testing datasets.
- **features.py**: Provides checks and descriptive string generations for a single delivery order, including calculating average speed.
- **model.py**: Manages the machine learning lifecycle by handling the training, evaluation, saving, and loading of the scikit-learn model.
- **validate.py**: Verifies that an individual order contains valid, logically sound data before processing.
- **train.py**: Acts as the command-line entry point to run the end-to-end pipeline, which trains the model, reports its error, and saves it to disk.
- **predict.py**: Serves as a command-line script that loads the saved model and generates a single prediction for a predefined delivery order.
